THE PROBLEM

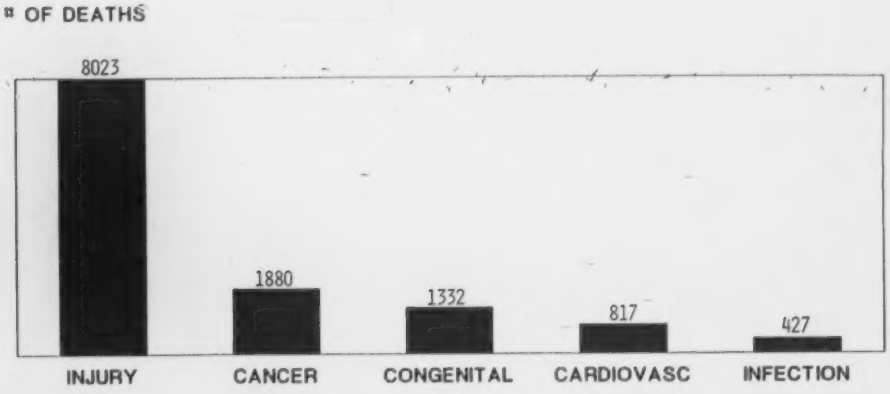
Injuries are the leading cause of childhood death in the United States. During this century, trauma has replaced infectious disease as the most important threat to our children (Figure 1). Injuries now claim approximately 10,000 lives each year among children ages 0-14 (18). In addition to fatal injuries, disabling or disfiguring injuries destroy the well-being and happiness of even larger numbers of youths.

We know a great deal about how to prevent many serious injuries. The most effective measures provide freedom from injury without requiring frequent cooperation or action on the part of parent or child. Promising examples include childproof fencing around home swimming pools, sprinkler systems to automatically extinguish housefires, air bags (automatically inflated restraints) for front seat occupants of motor vehicles, and playground equipment and surfaces that reduce the chance of disabling injury. Helmets

Figure 1

MAJOR CAUSES OF DEATH, AGES 1-14

United States, 1986



for bicyclists, child restraints, seat belts, and protective gear for children involved in sports activities are also effective. Tragically, this knowledge is not always applied.

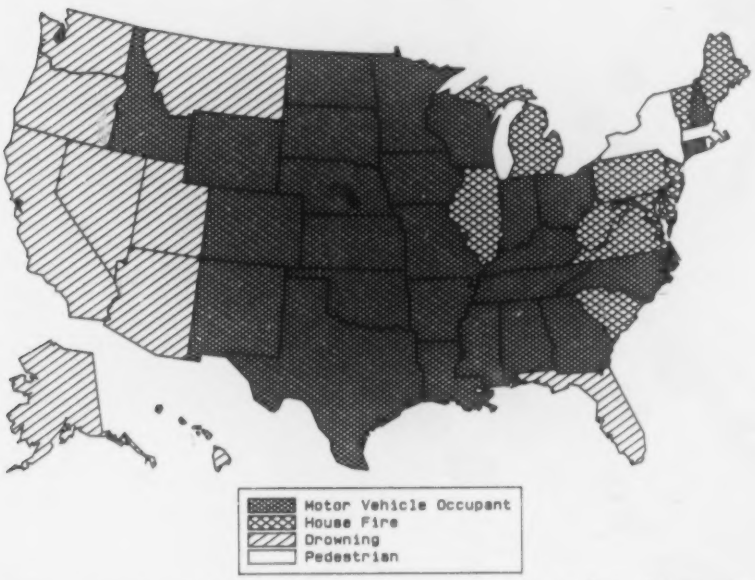
Sometimes people in a position to make changes do not know about the effective remedial possibilities. A book to be published soon (20) describes the steps that can be taken by people whose decisions influence the likelihood of childhood injury: school administrators, legislators and regulators, designers and manufacturers, health professionals, and public agencies. Other valuable sources of information on childhood injury prevention are listed in the Bibliography.

A recent survey reveals that with the sole exception of motor vehicle occupant injuries, none of the major causes of childhood injury mortality is addressed by the majority of state health departments (11). Sometimes prevention initiatives are hampered by lack of awareness of the importance of a given injury threat. In the past, policy makers have usually had to make decisions based on national data when developing local programs. Although national data are useful, state-specific data are valuable for recognizing special problem areas, setting priorities, gaining media attention, and convincing legislators, state agencies, and local groups of the need for action.

THE RESPONSE

Health agencies and others who are interested in children need a better picture of childhood injury mortality in their own states. This monograph is a response to that need. The picture varies dramatically from state to state, as this report shows, using data for the years 1980-1985. In more than half of all states, for example, children less than 15 years old are more likely to be killed as motor vehicle occupants than by any other means. Drownings are the most important cause in western states and Florida, and housefires are paramount in mid-Atlantic and some northern states (Figure 2).

FIGURE 2: LEADING CAUSE OF INJURY DEATH*
Ages 0–14 Years, 1980–1985



*When all categories of motor- vehicle deaths are combined, Total Motor Vehicle is the leading cause in EVERY state.

It is also necessary to identify the high risk groups of children in each state and the hazards that should be of primary concern. In illustration, for Black children the major cause of death nationally is house fires, but in California and several other states their major threat of death is from homicide. Comparisons among states help us to develop insight into some of the factors that contribute to injury. For example, drowning rates at ages 1-4 are highest in Florida and most western states (Figure 3A), a pattern unlike that for drowning at ages 10-14 (Figure 3B). The difference emphasizes the important role of swimming pools, which are especially apt to be involved in drownings of toddlers.

More important than ranking and comparing the states, however, is ranking the injury causes within each state and identifying the age, sex, and racial groups that are most often involved. These data will help states to identify their major injury problems and the high-risk groups of children for whom preventive efforts are especially necessary.

FIGURE 3A: DROWNING DEATH RATES
Ages 1–4 Years, 1980–1985, Deaths/100,000/Year

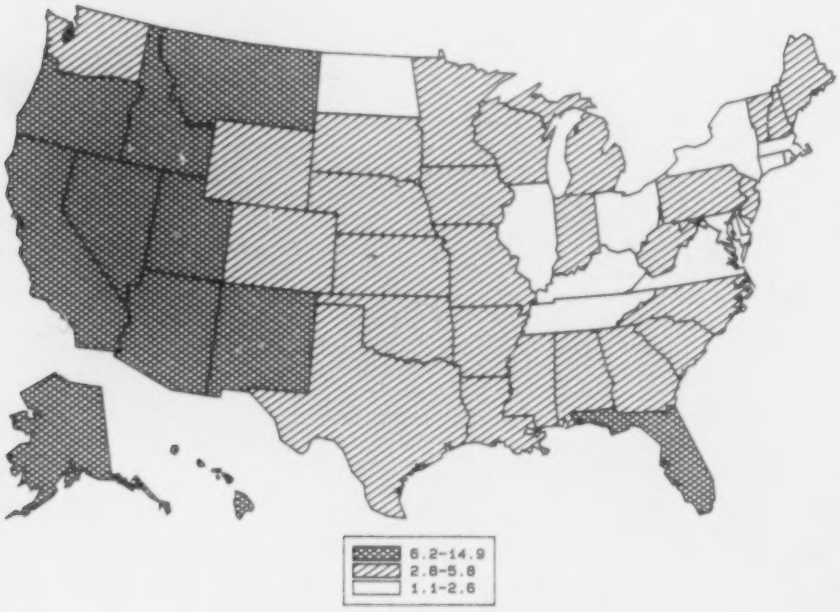


FIGURE 3B: DROWNING DEATH RATES
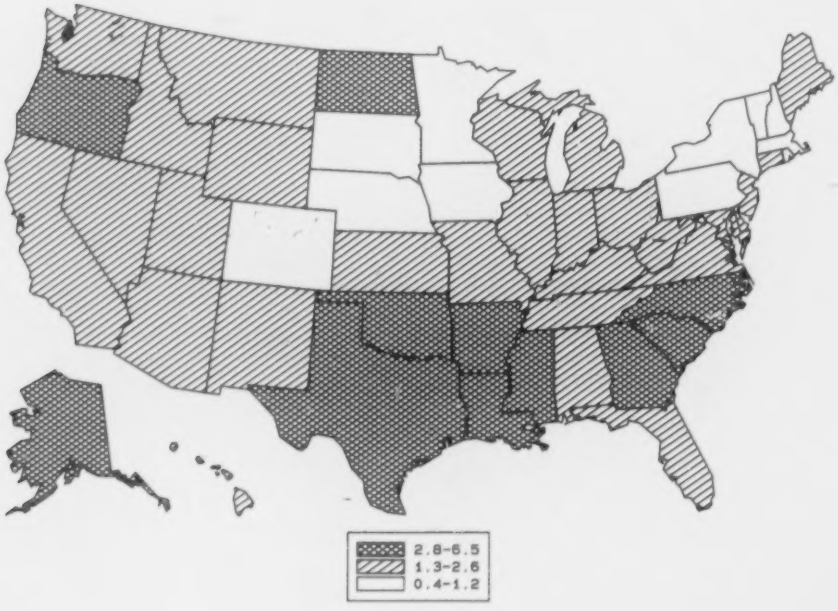
Ages 10–14 Years, 1980–1985, Deaths/100,000/Year

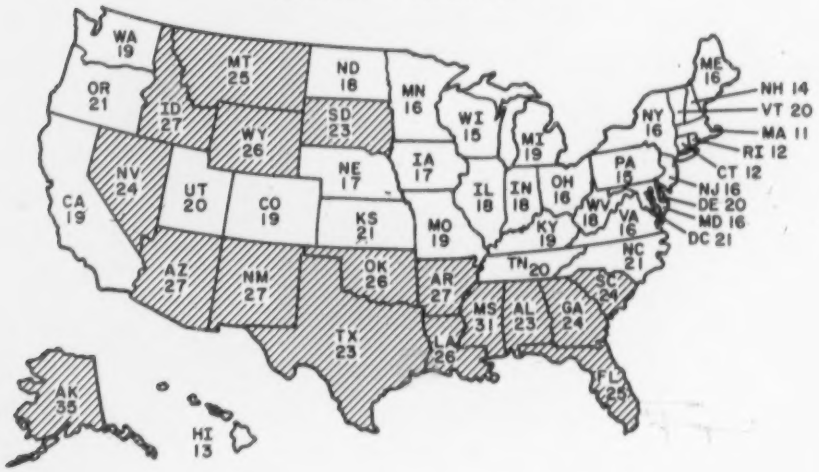


THE DATA

This report presents the numbers of deaths in each state and for the United States as a whole, by age, race, and sex for 23 causes of childhood injury. Figures 3 and 5-11 show the states with the highest and lowest death rates for 8 major causes of injury death. Maps for 5 other causes (motor vehicle occupant, housefire, unintentional firearm, homicide, and suicide) are included in a national overview (18).

Figure 4 presents the total injury death rate for each state, with darker shading for states with annual rates of 23/100,000 population or higher. (The total injury death rate for the United States as a whole was 19/100,000/year). The use of data from six years

FIGURE 4:
INJURY DEATH RATE BY STATE
Ages 0-14 Years, 1980 - 1985
(deaths/100,000/year)



made it possible to reduce the random variation caused by small numbers. However, chance alone might cause some state rankings to differ during another time period.

Death rates (the number of deaths per 100,000 children per year) are presented by age and sex for each state, and nationally for race. The 1982 Census Bureau population estimates, multiplied by six, were used as the denominators for annual death rate calculations. The Census Bureau does not provide population estimates by race for the individual states between decennial censuses; therefore we could not calculate race-specific mortality rates for each state using the 1982 population as a denominator.

In a few cases, the race of a child was unknown; these cases have been omitted from the tables with racial data. As a result, the totals will not always match the totals on other tables for the same state.

Individual states are encouraged to perform additional rate calculations using the numbers of deaths presented here. Using data in this monograph, the rate for each cause of injury may be readily calculated** and compared to the rate for the total United States. To calculate the death rates in their states for specific racial groups, agencies may use locally available population data for 1982 or, if necessary, 1980 census data.

We hope that states will supplement the information on childhood mortality in this monograph with local data on non-fatal injuries. Such data may be available from hospital discharge record systems, emergency rooms, poison control centers, and trauma registries. The large numbers of non-fatal falls and poisonings add importance to these problems, although they are not prominent as causes of childhood mortality. Regional variation is apt to be less dramatic for minor injuries than for fatal injuries. This means that data from various states on non-fatal injuries (2,5,9,10,16) may provide a useful guide to preventive efforts in many other states.

** The number of deaths from a specific cause divided by the total number of injury deaths times the state's total injury death rate.

THE CIRCUMSTANCES

Data are presented for 23 separate causes of injury and for all motor vehicle related injuries combined. The causes were defined on the basis of the "E codes," the External Causes of Injury in the International Classification of Diseases. The following brief descriptions of the 23 groupings are arranged in the order set forth in the Appendix.

Motor vehicle occupant deaths are those that occur in traffic and involve children who are passengers (or, occasionally, drivers) in cars or trucks. The category includes falls from vehicles and children killed when riding on the outside of the vehicles, for example in the back of pickup trucks. For the 1-14 year age group as a whole, motor vehicle occupant fatalities outrank all other injuries and diseases as the leading cause of death.

Pedestrian traffic deaths refer to children who are struck and killed on public roads when not in or on a motor vehicle or bicycle. Although most children are on foot, the category would also include any children on roller skates or skateboards. Pedestrian injuries are a universal problem, due to failure to separate pedestrian and vehicular traffic.

FIGURE 5: PEDESTRIAN – TRAFFIC DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year

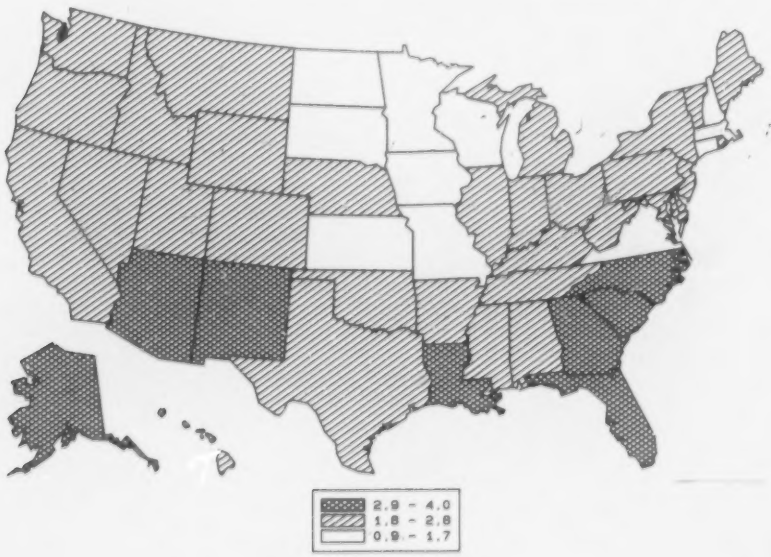


FIGURE 6: PEDESTRIAN – NON–TRAFFIC DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year

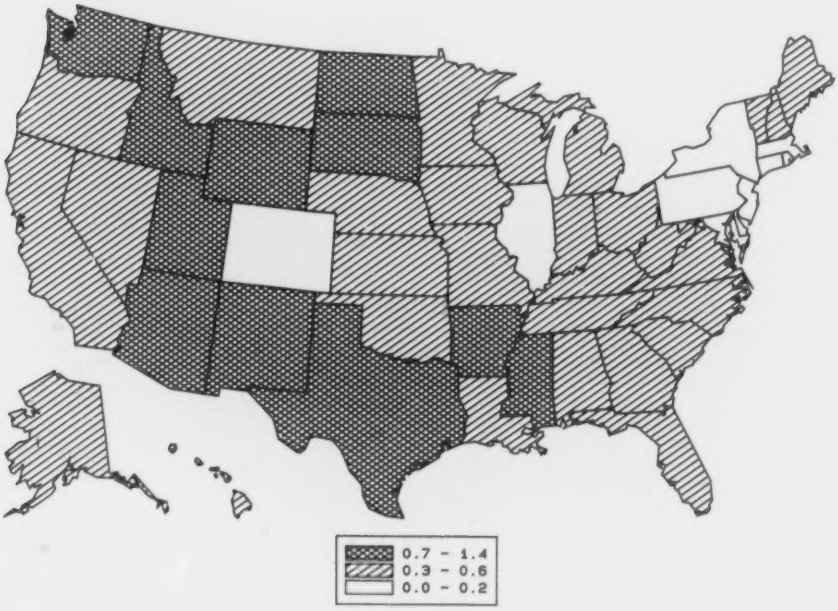

FIGURE 7: MOTORCYCLE DEATH RATES
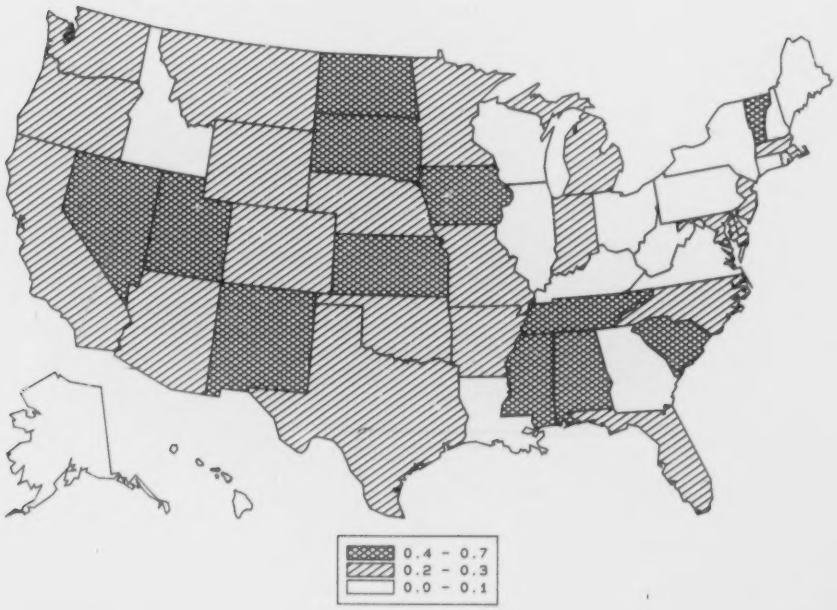
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year



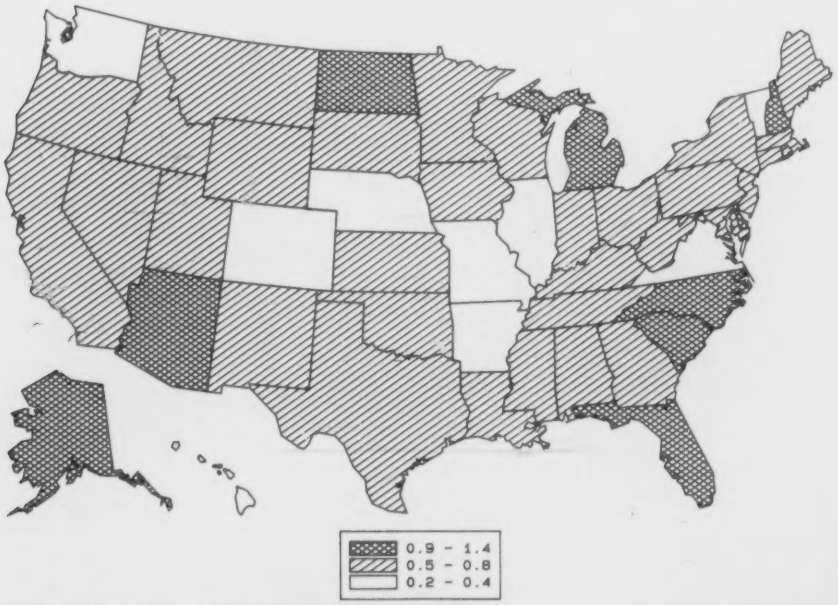
Death rates are especially high in urban areas, and therefore are high for some states such as New York, where a large proportion of children live in areas of high population density.

Pedestrian non-traffic deaths occur off of public roads, for example in driveways and parking lots. These deaths are most common in rural areas, especially in western states. Many are miscoded as pedestrian traffic deaths. Death rates are highest among one-year-old children. Frequently deaths in this category occur when children are run over by vehicles that are backing up.

Motorcyclist deaths include all children categorized as occupants (riders) of motorcycles, regardless of whether the injury occurred on public or private property. Two-thirds of the fatally injured children are listed as the operator of the motorcycle. Most deaths involve head injuries sustained in collisions with other motor vehicles. As a result of inadequate information, some deaths that are related to mopeds and minibikes may inadvertently be misclassified on death certificates as motorcyclist deaths.

Bicyclist deaths include any child on a vehicle that is operated solely by pedals,

FIGURE 8: BICYCLE DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year



and therefore exclude children riding motorized bicycles. The analyses are limited to deaths resulting from collisions with motor vehicles, because these represent 95% of all bicyclist deaths in childhood. The overwhelming majority of fatal injuries to bicyclists are head injuries.

Other motor vehicle related deaths include those involving all-terrain vehicles (ATVs), snowmobiles, mopeds, and minibikes. Large numbers of disabling injuries and deaths involving ATVs have been reported in recent years, but separate classification is not possible using currently available E codes.

Total motor vehicle related deaths include all deaths in the above six categories.

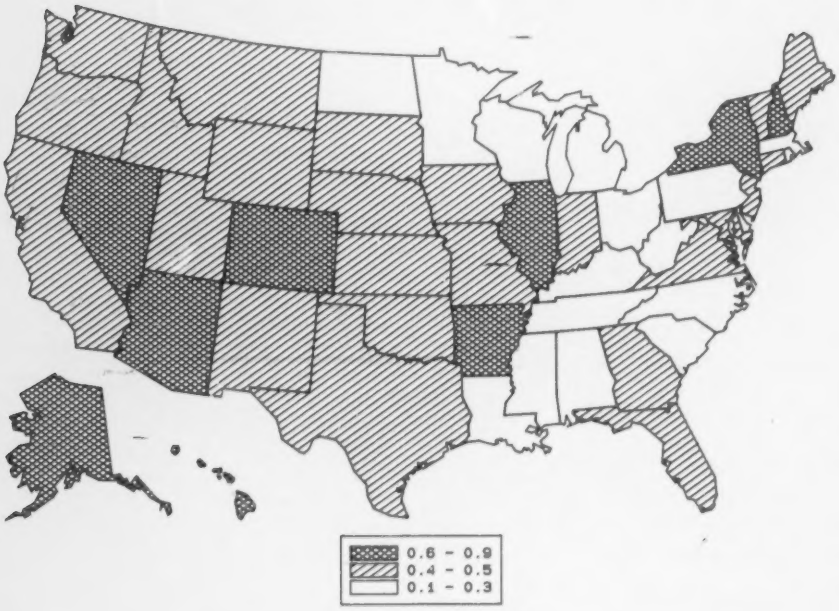
Air transport deaths include both commercial and private aviation, but the majority of the children killed are in private airplanes. Only 1% of the deaths are in unpowered aircraft, such as hang gliders.

Poisoning by solid or liquid, when fatal, typically involves medications or drugs (such as anti-depressants, methadone, and cardiovascular drugs) or petroleum products (such as kerosene). In older children, poisoning is often intentional; when deliberate self-poisoning is recognized, the event is classified as suicide.

Poisoning by gas or vapor usually involves carbon monoxide from motor vehicle exhaust or, less commonly, from defective home heaters. Most deaths in housefires are actually due to carbon monoxide poisoning from smoke inhalation, but such deaths are classified with fire deaths.

Falls, although the most common cause of injury, are rarely fatal unless a child falls from a height or the head strikes a hard surface, such as concrete. Falls from windows and other structures and falls down stairs in infant "walkers" are important causes of death

FIGURE 9: FALL DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year



and disability. Death rates are highest in infancy and are extremely low in children ages 5 or older.

Housefires cause 92% of all unintentional burn and fire-related deaths in children and therefore are analyzed as a specific category. Housefires are the major cause of death in Black children ages 1-9, and have high rates in eastern and southern states.

Drowning includes deaths related to boats (about 5% of childhood drownings) and drownings in bathtubs (about 8%). Rates are highest at ages 1-3, when most drownings involve swimming pools. Drowning is an especially large problem in western and southern states.

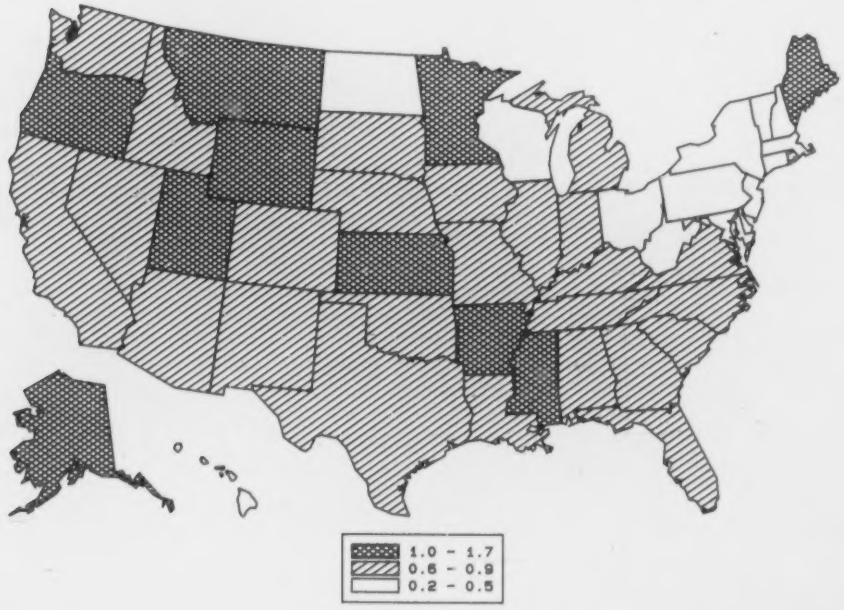
Aspiration of food into the respiratory tract is most likely to be fatal if the food is round (hot dogs, grapes, peanuts, round candies, etc.). This category also includes aspiration of regurgitated food, which in a sick or debilitated infant or child may be a terminal event.

Aspiration of other materials, as in the case of food, is most likely to cause fatal obstruction of the airway if the material is round (e.g., balls, nipples from nursing bottles). Balloons and pieces of plastic are other examples of choking hazards.

Suffocation occurs when the mouth and nose are covered (e.g., by a plastic bag or fallen earth) or when oxygen is not available for other reasons. Some deaths occur when a child cannot breathe because of external pressure (e.g., if an adult rolls over on a child in the same bed). More than one-third of suffocation deaths occur in a crib or bed. About 3% involve entrapment in an airless space such as a refrigerator. Strangulation is also included in this category, and may be caused by a cord attached to a toy, pacifier, or garment.

Unintentional firearm deaths constitute about 40% of all gun deaths in the 0-14 year age group. The death rate is highest in teen-age males. Southern and northwestern states have high rates. For all categories of intent (unintentional, suicidal, and homicidal),

FIGURE 10: SUFFOCATION DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year



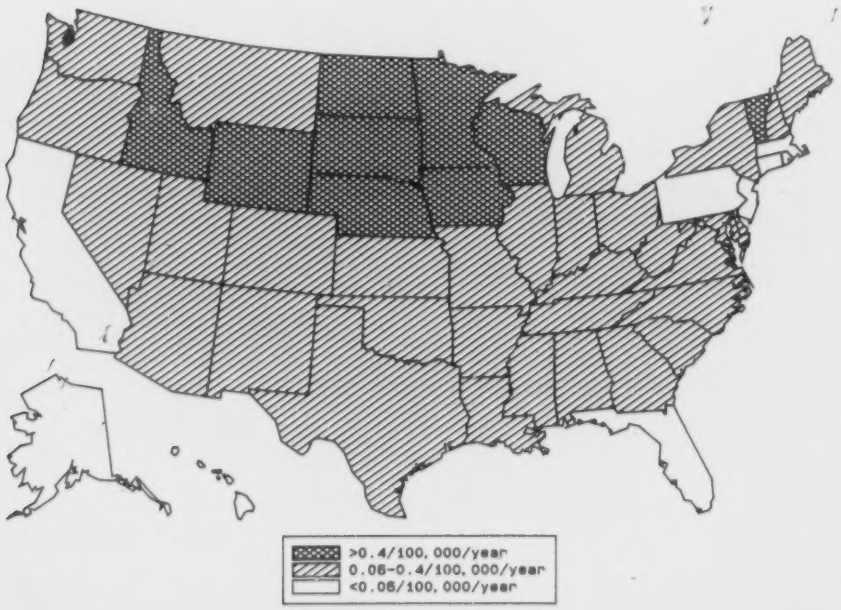
guns cause about 650 deaths annually in children ages 0-14; gun-related deaths are outranked only by deaths related to motor vehicles, drowning, and housefires.

Electric current fatalities among children occur at home in about half of all cases. In about one-tenth of all cases, they involve contact with transmission lines.

Farm machinery causes about 85% of all machinery-related deaths in children and therefore is separately categorized. It is a major cause of childhood death in many farm states. Children ages 3-4 have high death rates, most often involving falls from tractors being operated by adults.

Medical or surgical deaths include those resulting from mistakes during medical or surgical care (which cause about 12% of deaths in this category), adverse reactions to drugs (10%), or, most commonly, surgical or medical procedures that result in abnormal reactions in a patient.

FIGURE 11: FARM MACHINERY DEATH RATES
Ages 0–14 Years, 1980–1985, Deaths/100,000/Year



Other unintentional deaths are all those in the 800-949 range of E codes that are not specified above. Included are deaths from falling objects (about 80 annually), burns other than those from housefires (75), pedestrians killed by trains (27), children killed by a moving object or person (e.g., a baseball bat, air rifle pellet, or football player) (20), floods (20), animals being ridden (20), and falls from bicycles (20).

Suicide includes all deaths from intentionally self-inflicted injury. Death rates increase rapidly in the early teens. More than half of the suicides in young adolescents are by firearms and about one-third are by hanging.

Homicide includes deaths from child abuse, arson, and other intentional injuries such as those from shooting, strangulation, drowning or knifing. Firearms are the most frequently used weapon. Homicide is the leading cause of injury death in the first year of life.

Unknown intent refers to deaths in which it is not determined whether the injury was unintentional or deliberately inflicted by the deceased or another person. Most of these deaths involve burns, drowning, or firearms.
